

1 IMAGE PAIR

2 REAL DATA FLOW

Pose updates change anchors; appearance gradients never update the tracker.

1 IMAGE PAIR

2 REAL DATA FLOW

Pose updates change anchors; appearance gradients never update the tracker.

Why the supervision camera shares the anchor

Coordinate control and refinement loop

Before a loop closure

Local map and camera use keyframe k.
Their relative transform is fixed.

$$T_{WCf}^{-1} T_{Wck} = T_{CkCf}^{-1}$$

Pose correction

The pose graph changes T_{Wck} .
The map and camera move together.

shared anchor: relation preserved

Controlled 6% scale test

Fixed world camera: refinement reverses the correction.
Shared anchor: correction remains after about 500 steps.

Desk + room controls

REFINEMENT LOOP

sample RGB

compose pose

render map

L1 + SSIM

Adam update

Only Gaussian scale, rotation, opacity, and DC color receive gradients.

Qualitative reconstruction at common cameras

Measured renders; identical crops and scales

Ground truth

Photo-SLAM

MonoGS

Ours

TUM desk: two middle-ranked Ours-minus-MonoGS PSNR views

Orange panels are identical pixel crops across all methods.

Replica reconstruction across scenes

No monocular MonoGS artifact was available

All images use the same selected camera within each scene.

Opacity attenuation: relative LPIPS change (%)

Refiner on vs. off: PSNR gain (dB)

Interpretation

Refinement gives the largest controlled gain.
Opacity reduction is robust; confidence allocation is not.

External baseline comparison uses the released head with attenuation off.

Pairwise predictions become a persistent map

Editable paper teaser

Photo-SLAM

Splatt3R-SLAM

One keyframe anchor carries both the local Gaussian map and the cameras that refine it.

Real office0 render at a common evaluation camera

LEADING REPLICA RECONSTRUCTION

+3.54 dB vs Photo-SLAM

PSNR lead on all 8 Replica scenes
